Question:

Find all values of λ such that $x, y, z \neq (0,0,0)$ and

$$\left(\hat{i} + \hat{j} + 3\hat{k}\right)x + \left(3\hat{i} - 3\hat{j} + \hat{k}\right)y + \left(-4\hat{i} + 5\hat{j}\right)z = \lambda\left(x\hat{i} + y\hat{j} + z\hat{k}\right)$$

where $\hat{i}, \hat{j}, \hat{k}$ are unit vectors along the coordinate axes.

Solution:

The given vector equation is:

$$(\hat{i} + \hat{j} + 3\hat{k})x + (3\hat{i} - 3\hat{j} + \hat{k})y + (-4\hat{i} + 5\hat{j})z = \lambda(x\hat{i} + y\hat{j} + z\hat{k}) \tag{1}$$

First, we group the terms on the left-hand side by the unit vectors $\hat{i}$, $\hat{j}$, and $\hat{k}$:

$$(x + 3y - 4z)\hat{i} + (x - 3y + 5z)\hat{j} + (3x + y)\hat{k} = \lambda x\hat{i} + \lambda y\hat{j} + \lambda z\hat{k} \tag{2}$$

For the two vectors to be equal, their corresponding components must be equal. This gives us a system of three linear equations:

$$x + 3y - 4z = \lambda x \tag{3}$$

$$x - 3y + 5z = \lambda y \tag{4}$$

$$3x + y = \lambda z \tag{5}$$

We can rewrite the system of equations by moving the λ terms to the left side:

$$(1 - \lambda)x + 3y - 4z = 0 \tag{6}$$

$$x + (-3 - \lambda)y + 5z = 0 \tag{7}$$

$$3x + y - \lambda z = 0 \tag{8}$$

This is a homogeneous system of linear equations. It can be expressed in matrix form as $(A - \lambda I)\mathbf{v} = 0$, where:

$$A = \begin{pmatrix} 1 & 3 & -4 \\ 1 & -3 & 5 \\ 3 & 1 & 0 \end{pmatrix}, \quad I = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad \mathbf{v} = \begin{pmatrix} x \\ y \\ z \end{pmatrix} \tag{9}$$

The problem states that $(x, y, z) \neq (0, 0, 0)$, which means we are looking for a **nontrivial solution** for the vector $\mathbf{v}$. This is a **eigenvalue problem**. The values of λ for which non-trivial solutions exist are the eigenvalues of the matrix A.

A non-trivial solution exists if and only if the determinant of the coefficient matrix is zero. This gives us the characteristic equation:

$$|A - \lambda I| = 0 \tag{10}$$

$$\begin{vmatrix} 1 - \lambda & 3 & -4 \\ 1 & -3 - \lambda & 5 \\ 3 & 1 & -\lambda \end{vmatrix} = 0 \tag{11}$$

Now, we calculate the determinant by expanding along the first row:

$$(1 - \lambda)\begin{vmatrix} -3 - \lambda & 5 \\ 1 & -\lambda \end{vmatrix} - 3\begin{vmatrix} 1 & 5 \\ 3 & -\lambda \end{vmatrix} + (-4)\begin{vmatrix} 1 & -3 - \lambda \\ 3 & 1 \end{vmatrix} = 0 \tag{12}$$

$$(1 - \lambda)((-3 - \lambda)(-\lambda) - 5) - 3(-\lambda - 15) - 4(1 - 3(-3 - \lambda)) = 0 \tag{13}$$

$$(1 - \lambda)(\lambda^2 + 3\lambda - 5) + 3(\lambda + 15) - 4(10 + 3\lambda) = 0 \tag{14}$$

$$(\lambda^2 + 3\lambda - 5 - \lambda^3 - 3\lambda^2 + 5\lambda) + (3\lambda + 45) - (40 + 12\lambda) = 0 \tag{15}$$

$$-\lambda^3 - 2\lambda^2 + 8\lambda - 5 + 3\lambda + 45 - 40 - 12\lambda = 0 \tag{16}$$

Combine like terms to get the characteristic polynomial:

$$-\lambda^3 - 2\lambda^2 - \lambda = 0 \tag{17}$$

$$\lambda^3 + 2\lambda^2 + \lambda = 0 \tag{18}$$

Factoring out λ:

$$\lambda(\lambda^2 + 2\lambda + 1) = 0 \tag{19}$$

The quadratic term is a perfect square:

$$\lambda(\lambda + 1)^2 = 0 \tag{20}$$

The solutions for λ are:

$$\lambda = 0 \quad \text{or} \quad \lambda = -1 \tag{21}$$

Thus, the required values of λ are 0 and -1.
